Current understandings on dust formation in supernovae

Takaya Nozawa

(NAOJ, Division of theoretical astronomy)

Main collaborators:

Masaomi Tanaka (NAOJ, theory)
Keiichi Maeda (Kyoto University)
Takashi Kozasa, Asao Habe (Hokkaido University)
Hideyuki Umeda (University of Tokyo)
Ken'ichi Nomoto (Kavli IPMU)

0-1. My research interests

- Formation of dust in the ejecta of supernovae
- Dynamics, destruction, and heating of dust grains in high-velocity shock waves
- Evolution of grain size distribution in galaxies and interstellar extinction curves
- Origin of dust grains in the early universe and the roles of dust in star formation
- Formation of dust in stellar winds and mass-loss history at late phases of stellar evolution

0-2. Introduction

・SNe are important sources of interstellar dust?

- abundant metal (metal : N > 5)
- low temperature (T < ~2000 K)
- high density ($n > \sim 10^6$ cm^{-3})

➔ mass-loss winds of AGB stars

expanding ejecta of supernovae

- huge amounts of dust grains ($>10^8$ M_{sun}) are detected in host galaxies of quasars at redshift z > 5

➔ 0.1 M_{sun} of dust per SN is needed to explain such massive dust at high-z (e.g. Dwek et al. 2007)

- contribution of dust mass from AGB stars and SNe

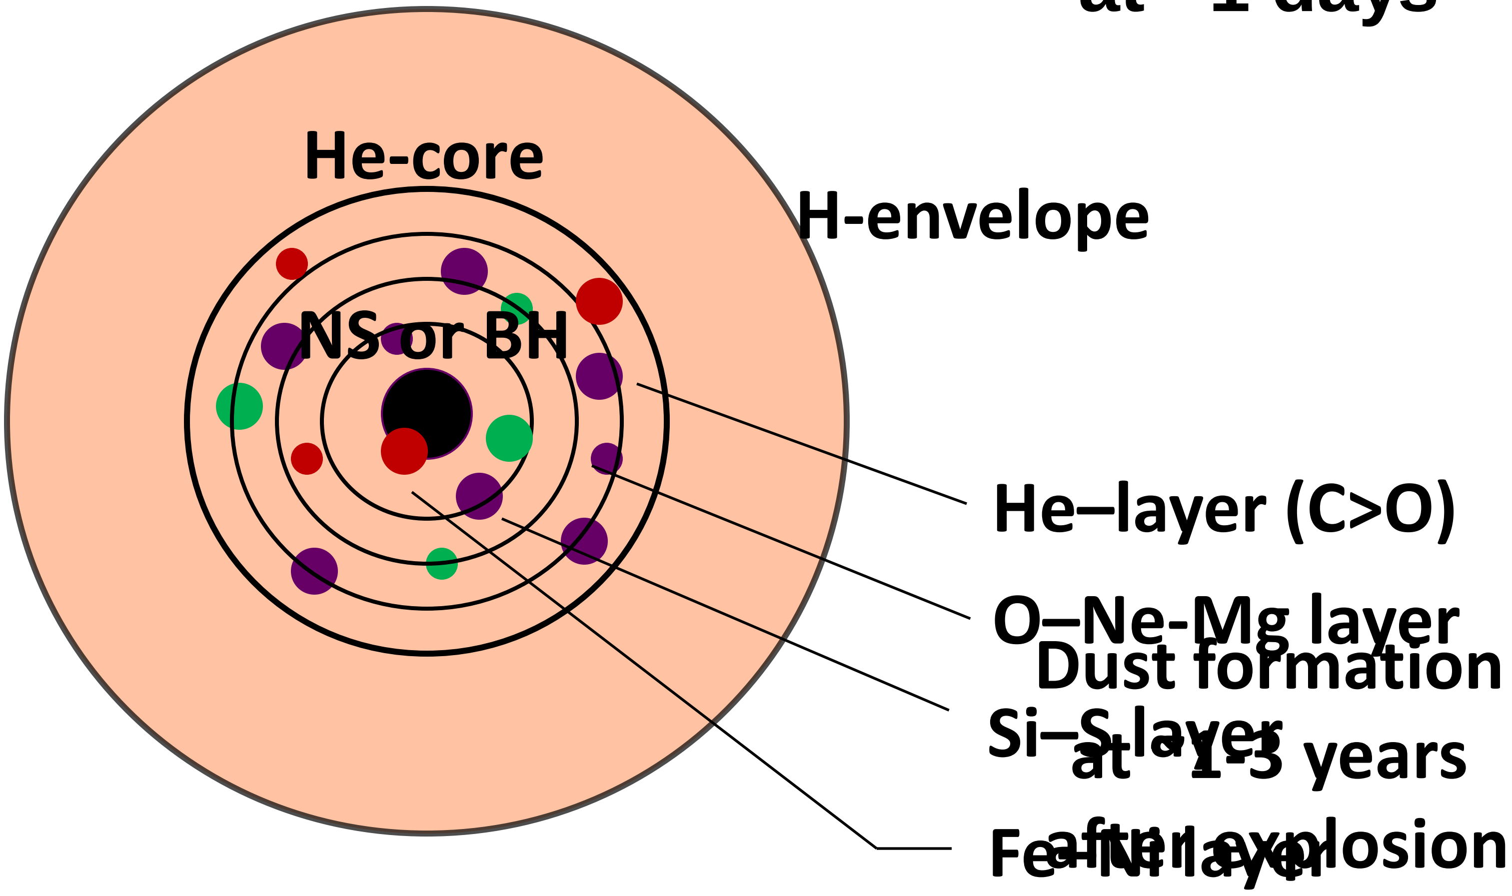
n(AGB stars) / n(SNe) ~ 10-20

M_{dust} = 0.01-0.05 M_{sun} per AGB (Zhukovska & Gail 2008)

M_{dust} = 0.1-1.0 M_{sun} per SN (e.g., Nozawa et al. 2003, 2007)

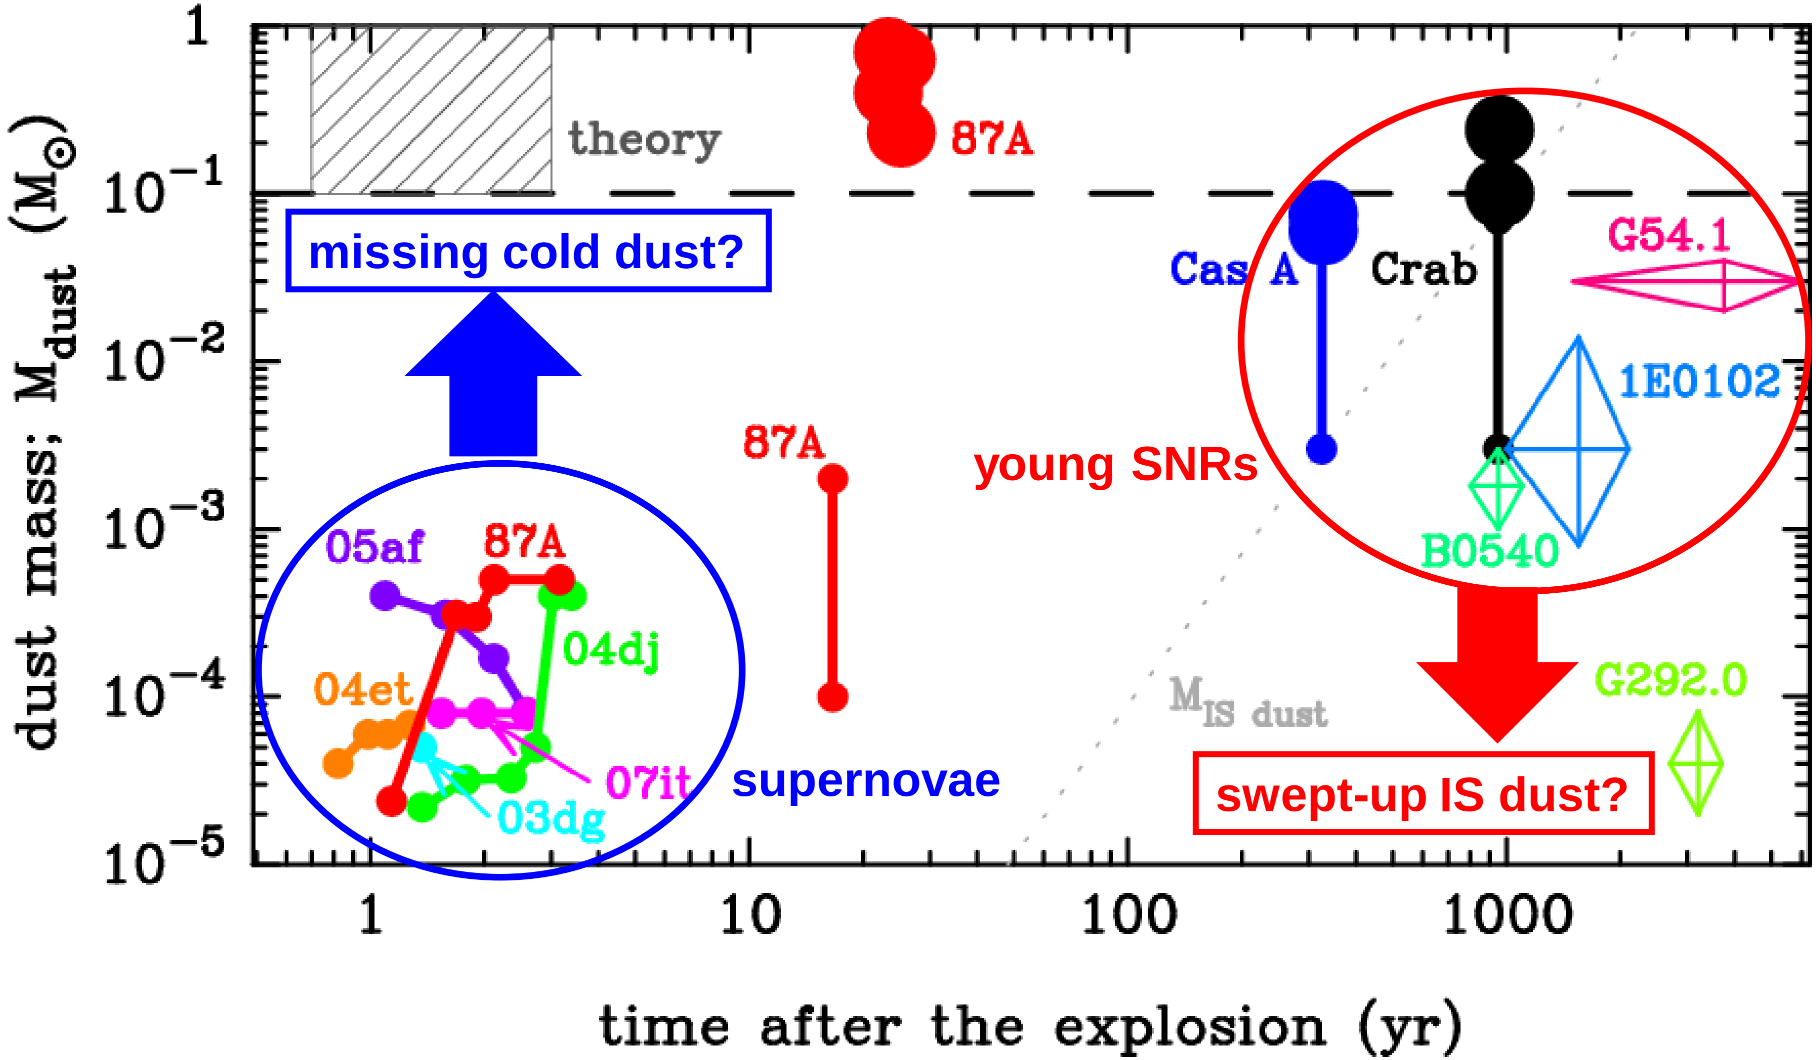
Dust Formation in the ejecta of SNe

at ~1 days



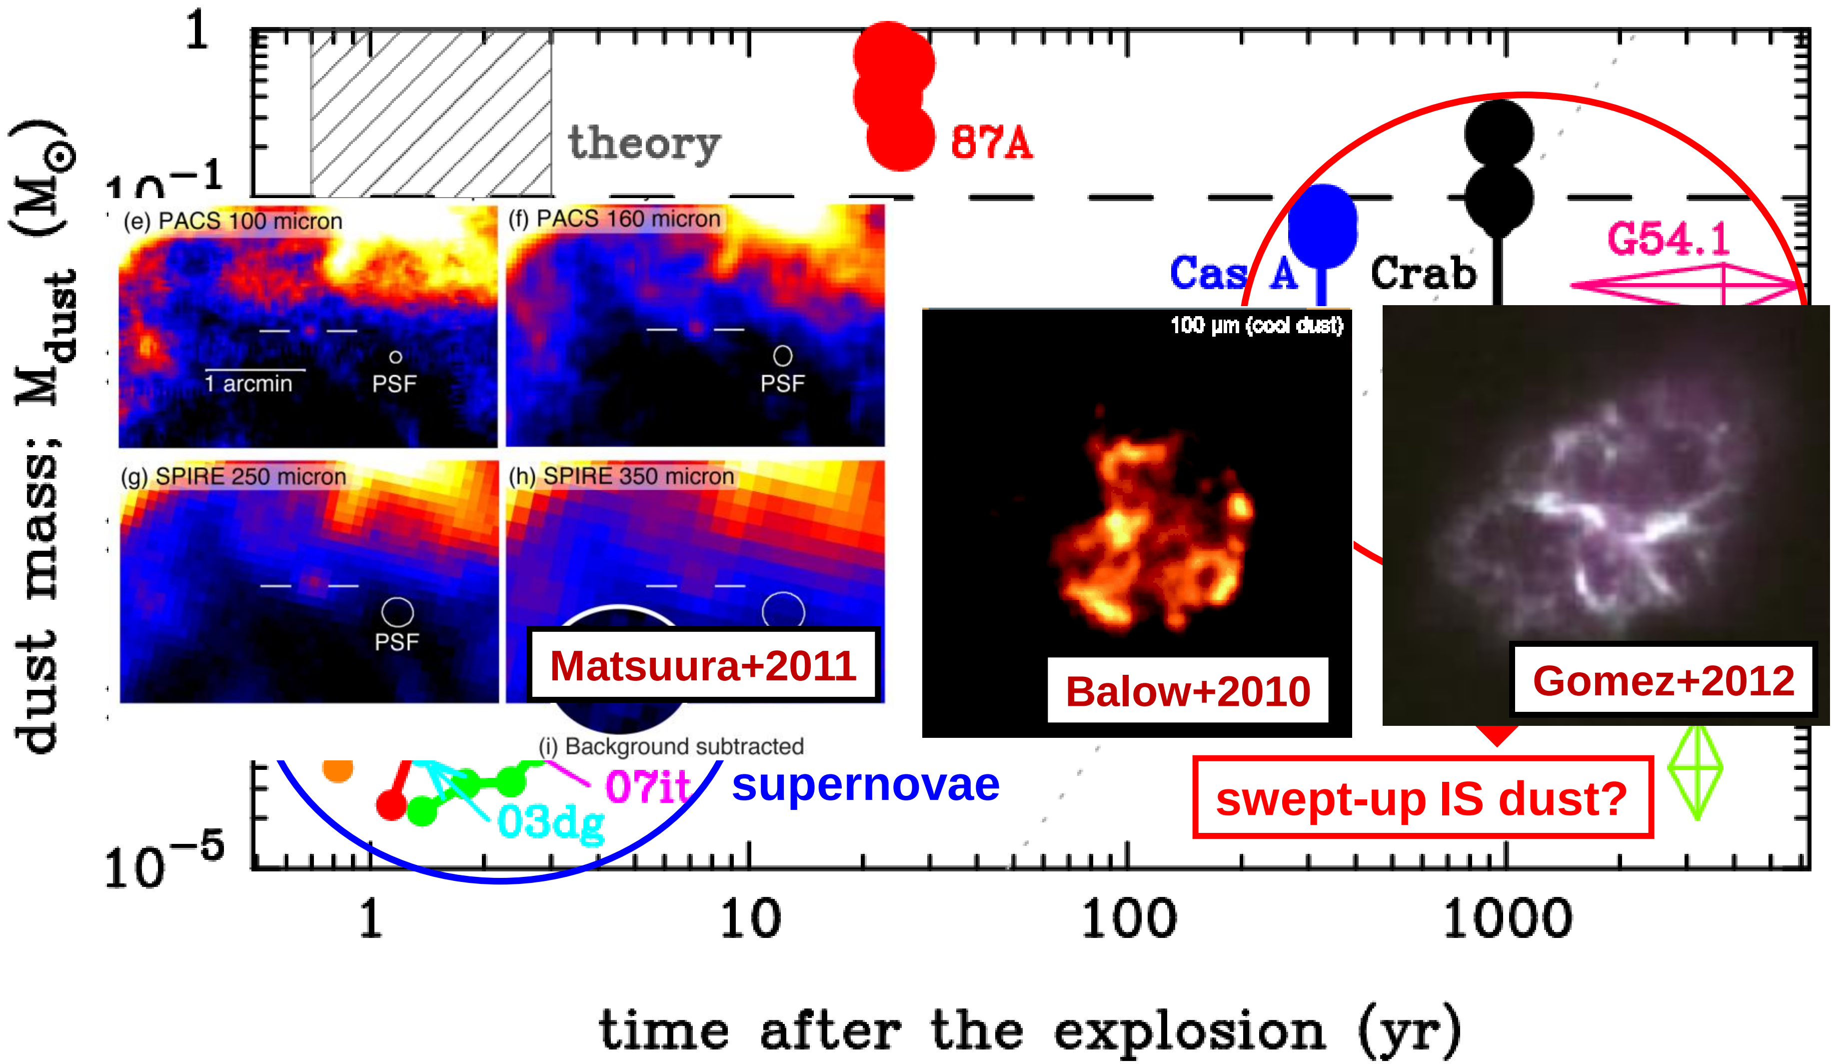
1. Observations of Dust Formation in SNe (and SNRs)

1-1. Summary of observed dust mass in CCSNe



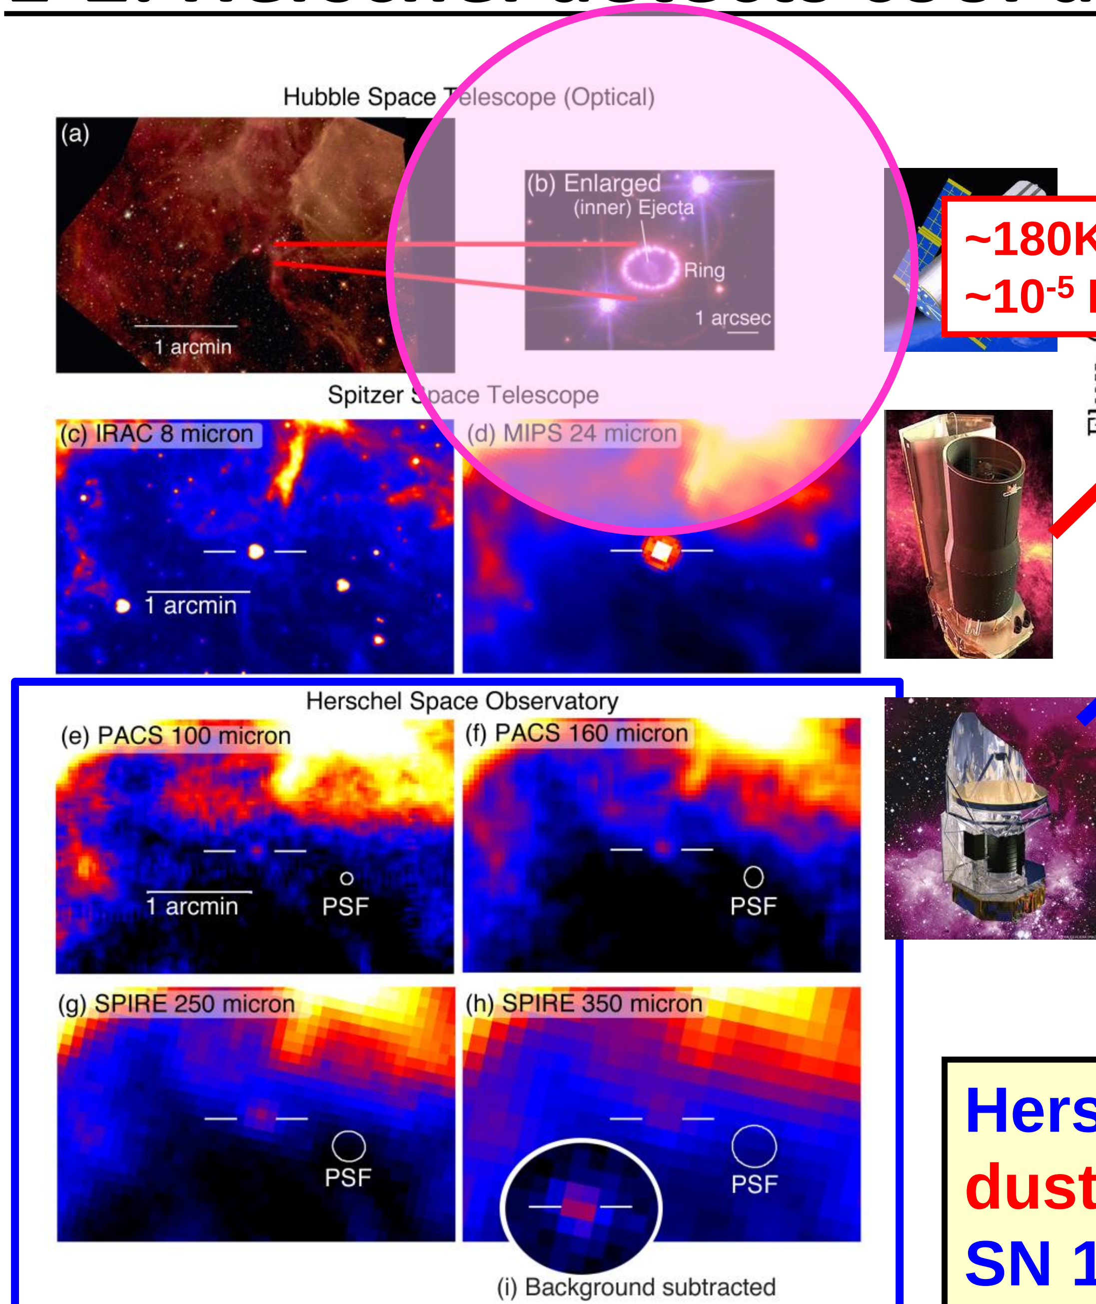
Far-IR to sub-mm observations are essential for revealing the mass of dust grains produced in the ejecta of SNe

1-1. Summary of observed dust mass in CCSNe

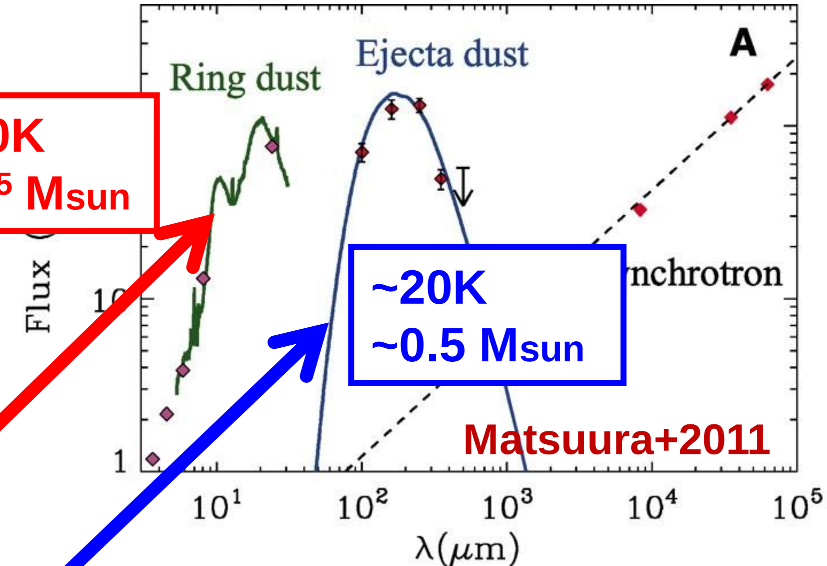


Far-IR to sub-mm observations are essential for revealing the mass of dust grains produced in the ejecta of SNe

1-2. Herschel detects cool dust in SN 1987A

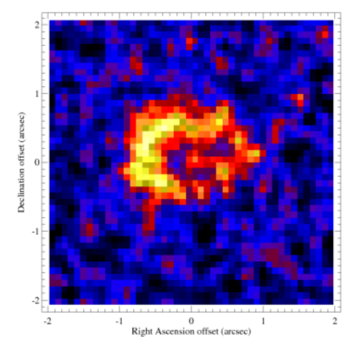


~180K
~10^{-5} Msun



~20K
~0.5 Msun

Matsuura+2011



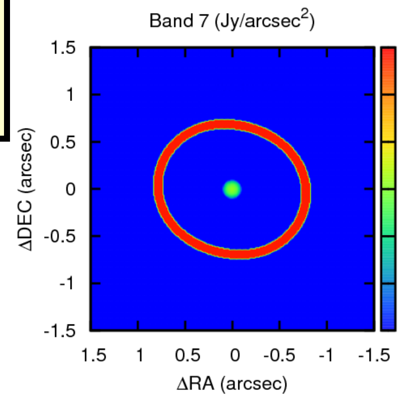
on 4 Oct 2003
Gemini T-ReCS
(λ = 10.36 μm)
2 pixels : 0.18”
(Bouchet+04)

Herschel detects cool (~20K) dust of ~0.4-0.7 Msun toward SN 1987A!

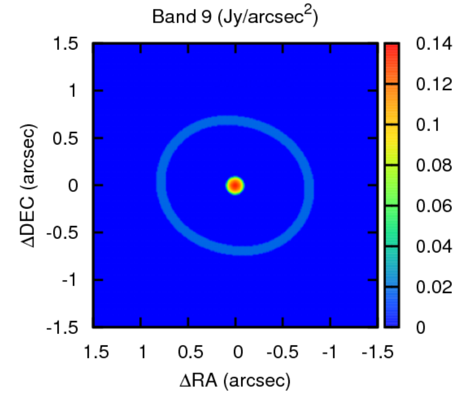
1-3. Resolving cool dust in SN 87A with ALMA

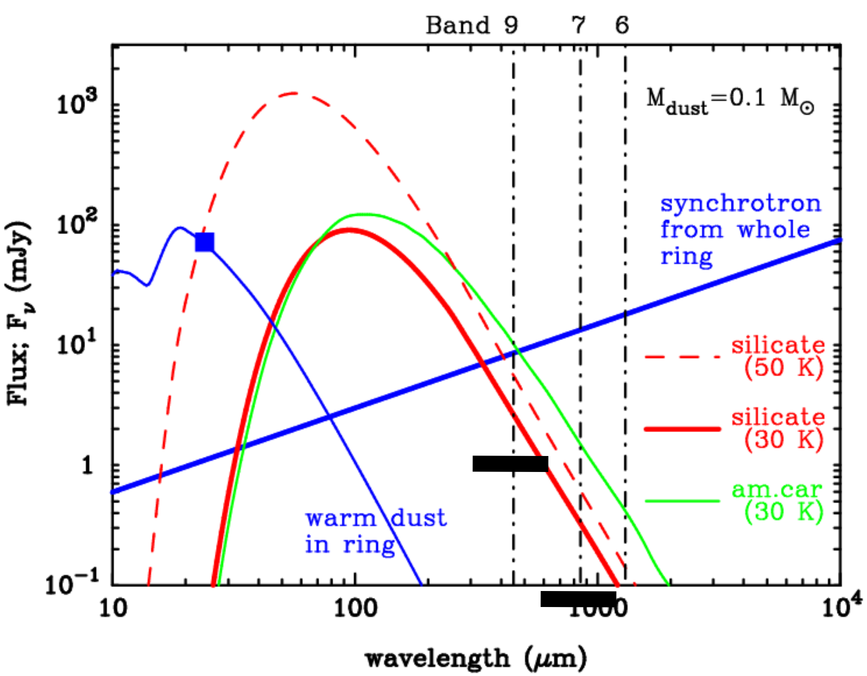
ALMA Cycle 0 Proposal
'Detecting cool dust in SN1987A'
(TN, Tanaka, et al.)

Band 7 (850 μm)

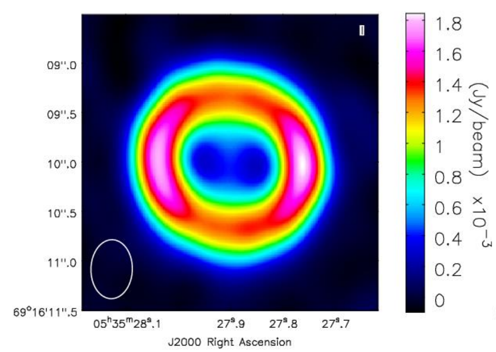


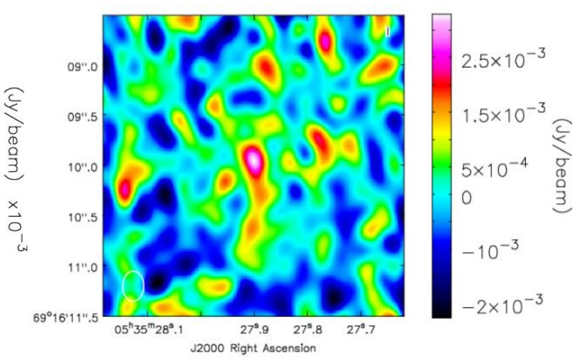
Band 9 (450 μm)





CASA simulation with extended config. (4 hrs)





0.1 Msun of silicate
➔ 5σ detection at Band 9 !!

1-4. Successful ALMA proposals for SN 1987A

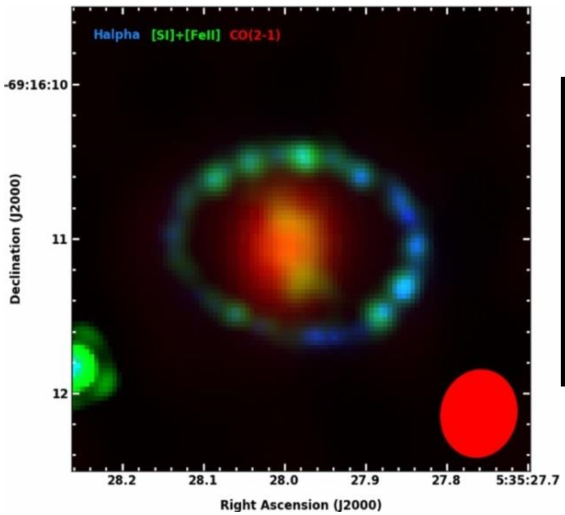
Band 3, 6, 7, 9 compact configuration

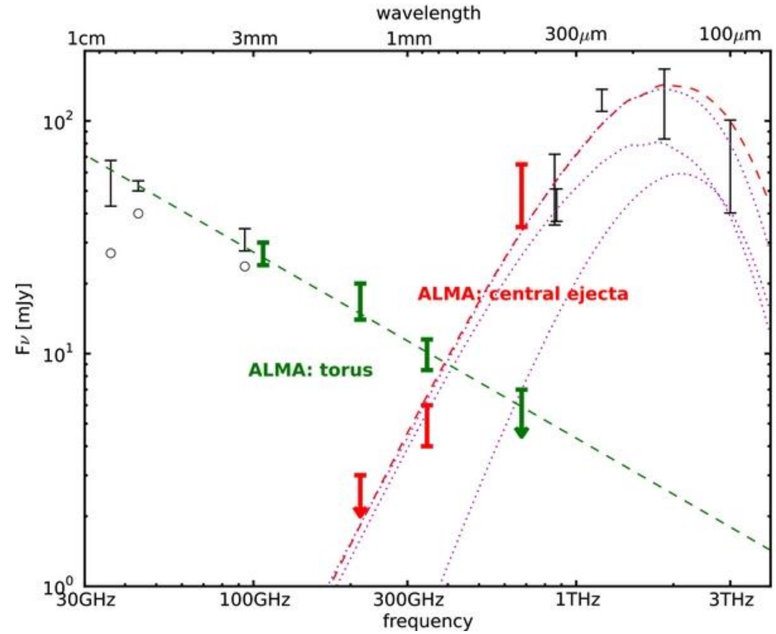
1-5. ALMA reveals dust formed in SN 1987A



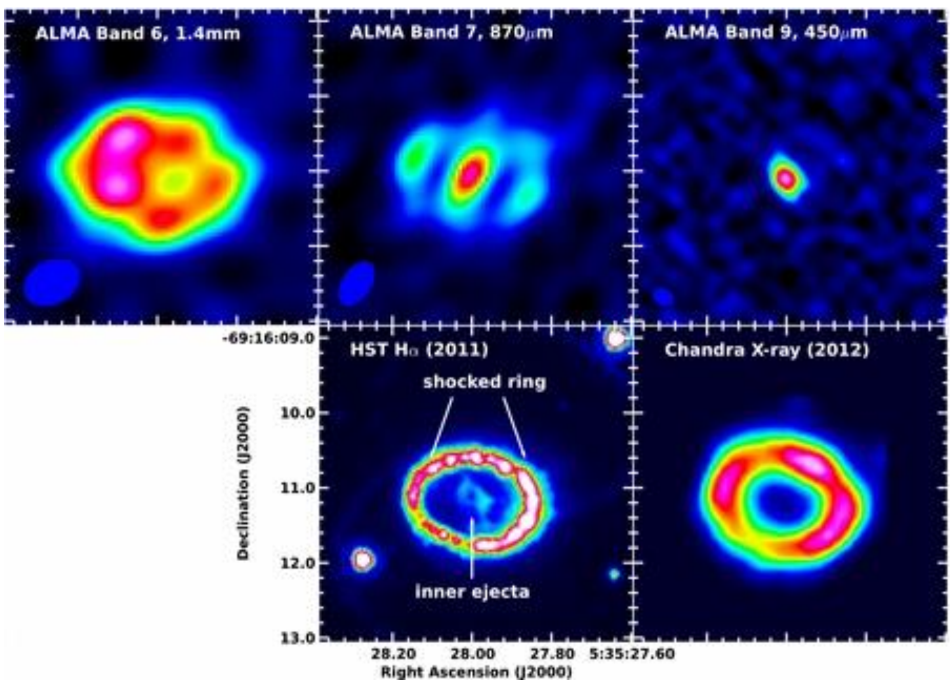
blue: Hα
green: 1.6 μm
red: CO(2-1)

➜ >0.1 Msun of CO

SED of 25-years old SN 1987A



Indebetouw+2014



ALMA spatially resolves cool (~20K) dust of ~0.5 Msun formed in the ejecta of SN 1987A

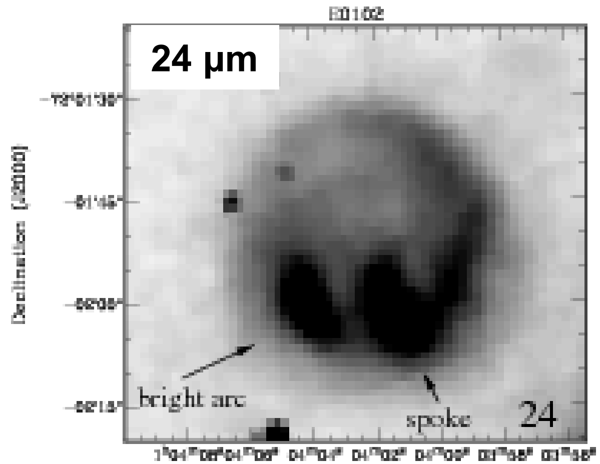
➔ SNe could be production factories of dust grains

1-6. Possible target: SNR 1E0102-72.3 in SMC

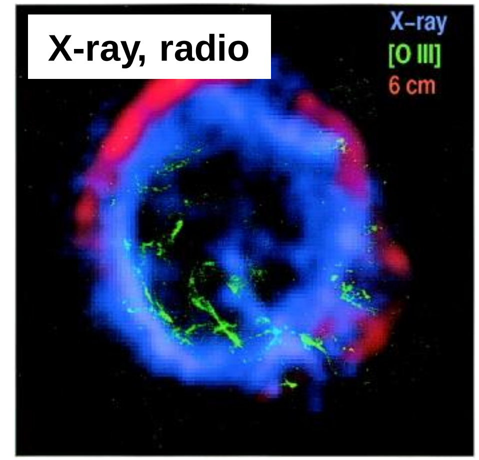
young (compact) supernova remnants in LMC/SMC !

・ SNR 1E0102-72.3

- O-rich (Type Ib?)
- age : ~1000 yr
- Mwarm ~ 10^{-3} Msun
- Mcool ~ ???



Stanimirovic+05

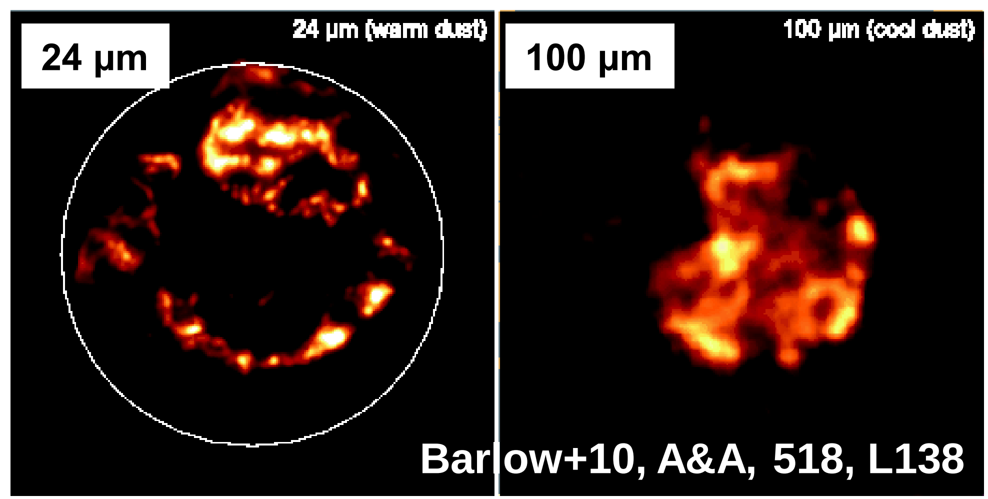


Gaetz+00

・ Cassiopeia A

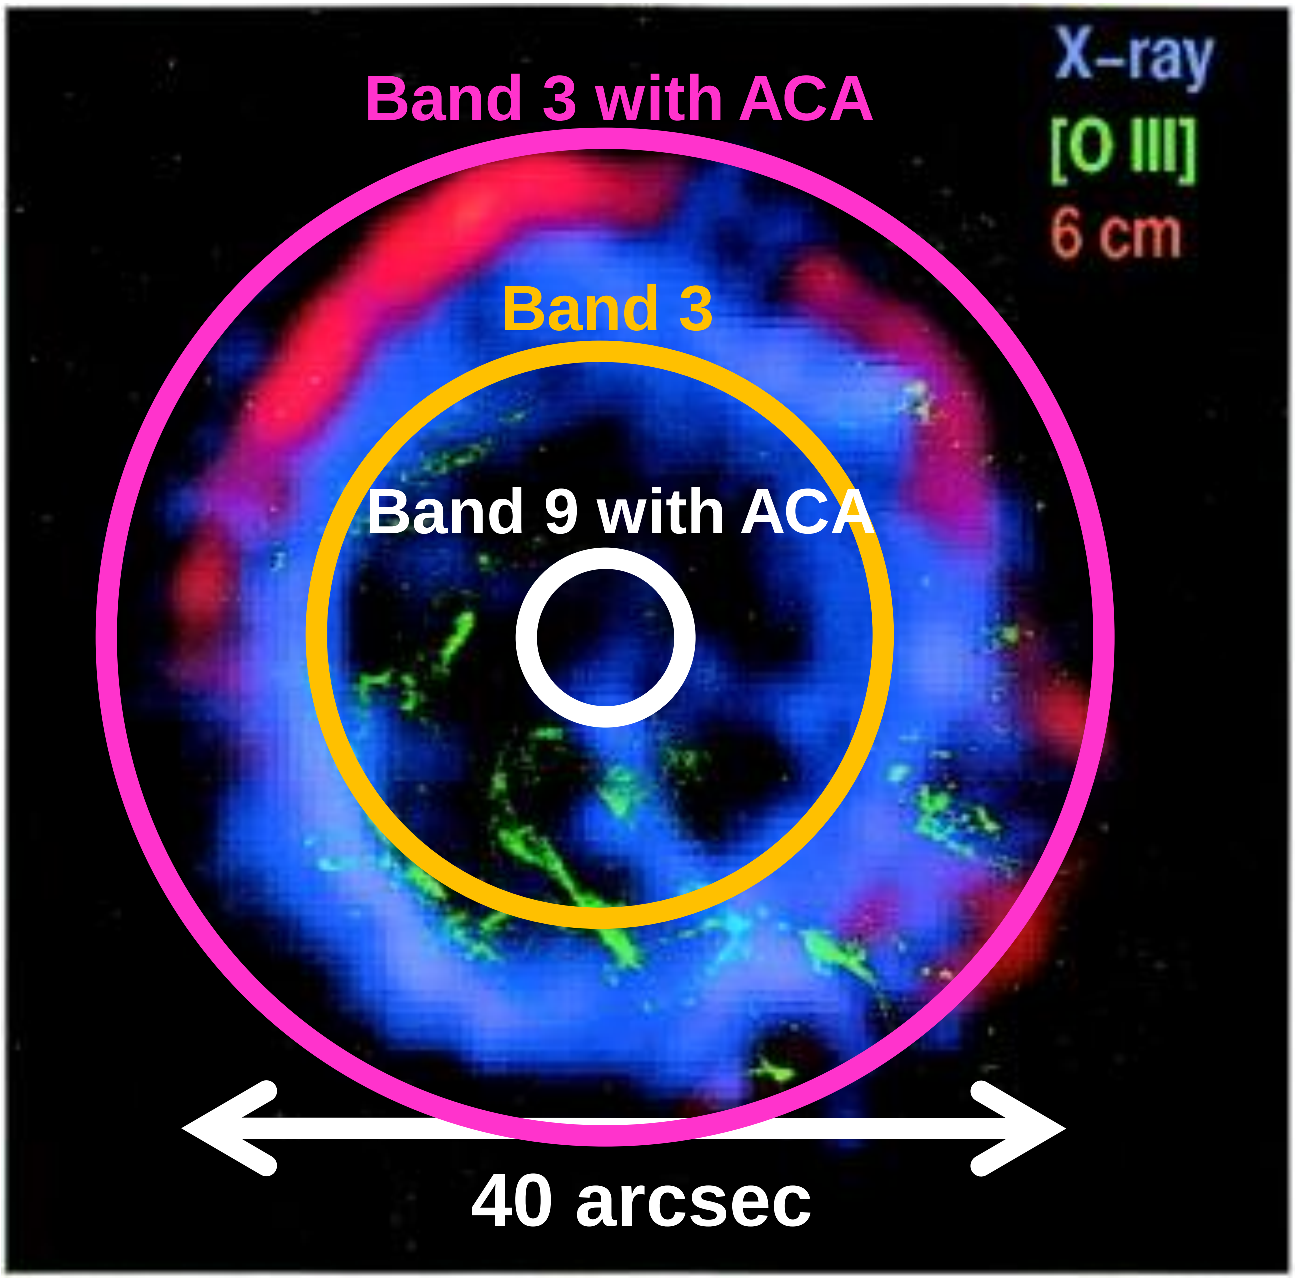
- O-rich (Type IIb)
- age : 330 yr
- Mwarm < 10^{-2} Msun
- Mcool ~ 0.07 Msun

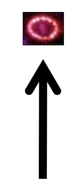
Cas A model (Nozawa+10)



Barlow+10, A&A, 518, L138

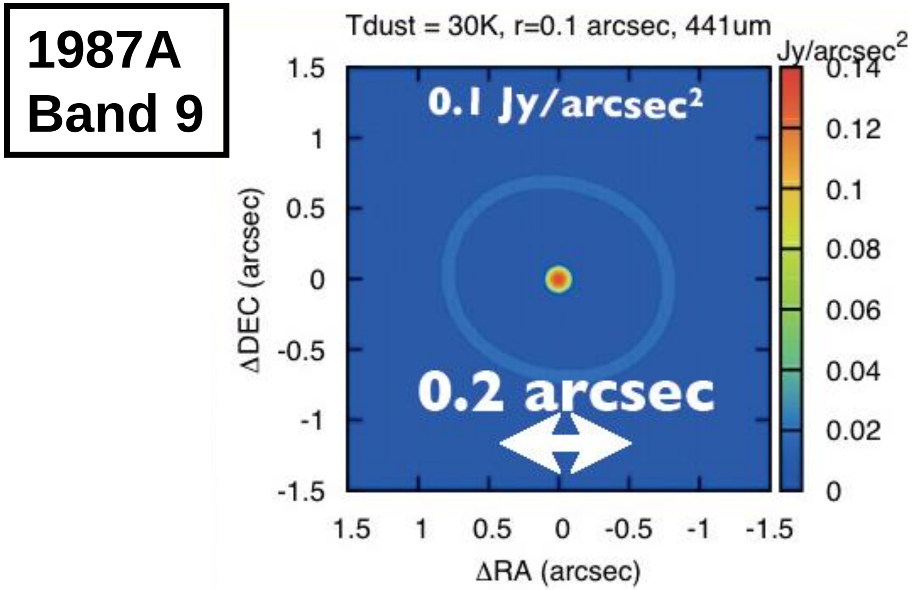
1-7. SNR 1E0102-72.3 is too extended!

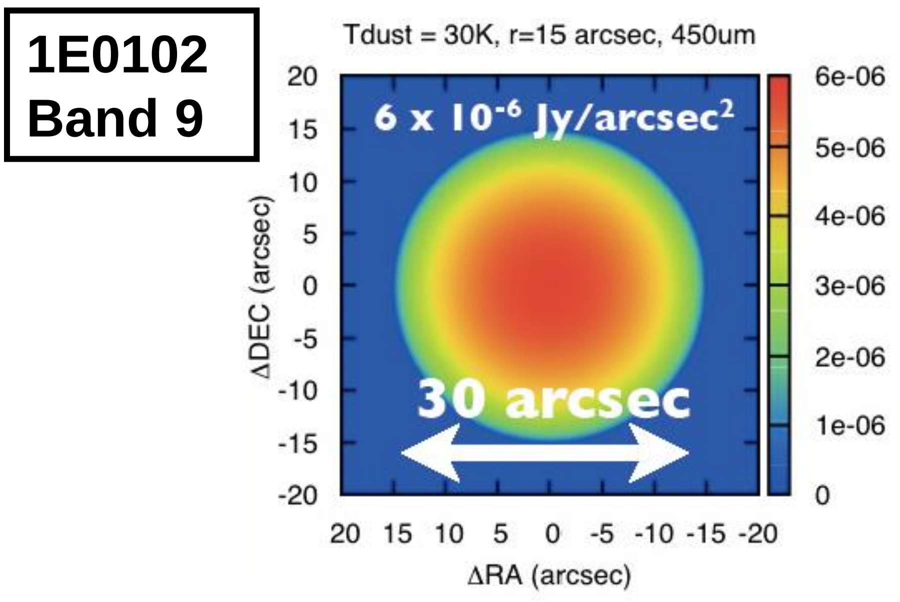


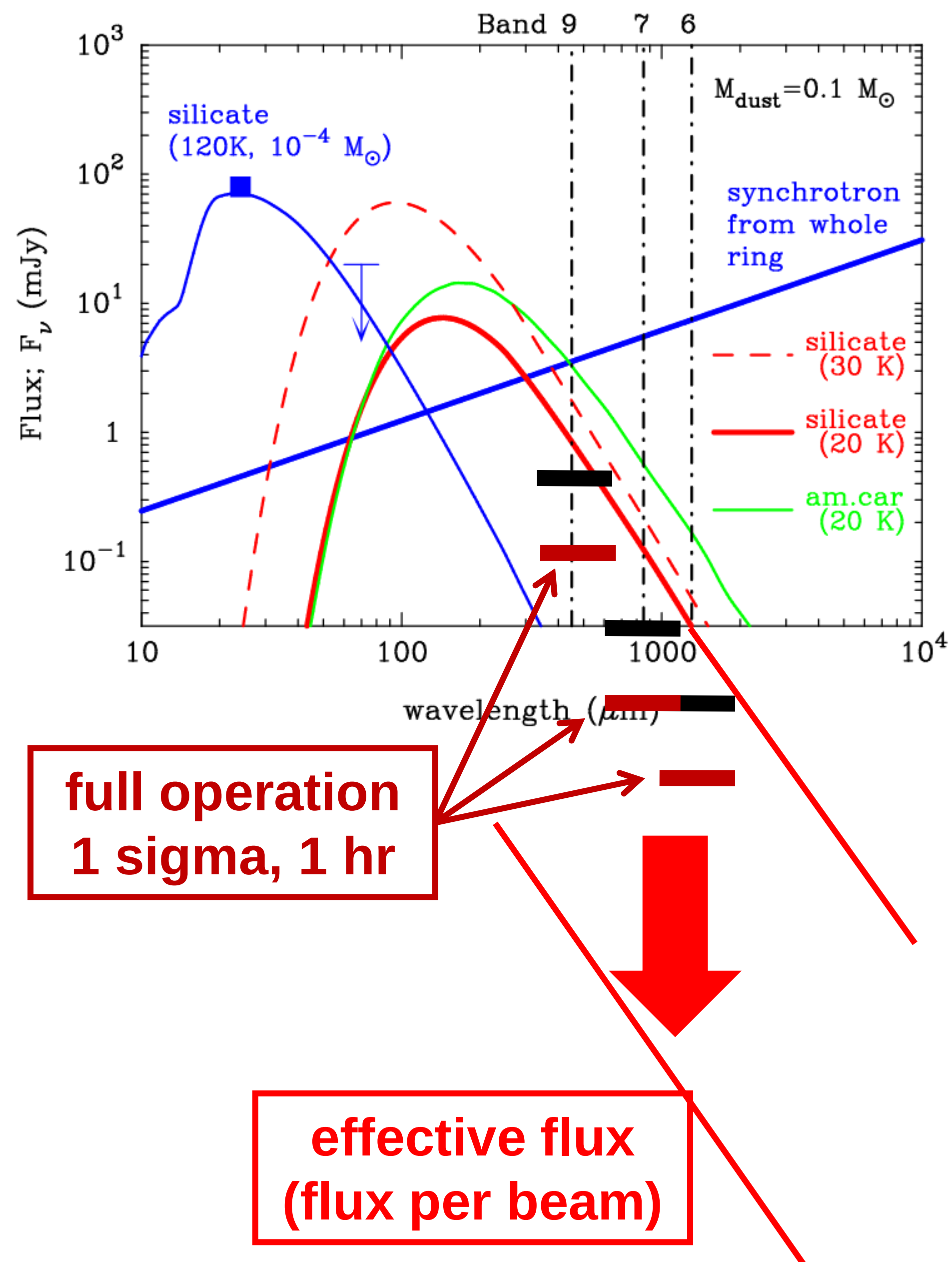


SN 1987A

1-8. Flux estimates necessary for detection







1-9. Summary of observations of SN dust

- ALMA confirmed the presence of huge amounts of newly formed dust in the ejecta of SN 1987A
  - ➜ heavy elements (Si, Mg, Fe, C) are locked up in dust grains
  - ➜ SNe are main production factories of dust grains

- It seems too hard to detect thermal emission from cool dust in any other SNe/SNRs with ALMA
  - ➜ young SNRs in LMC/SMC are too extended

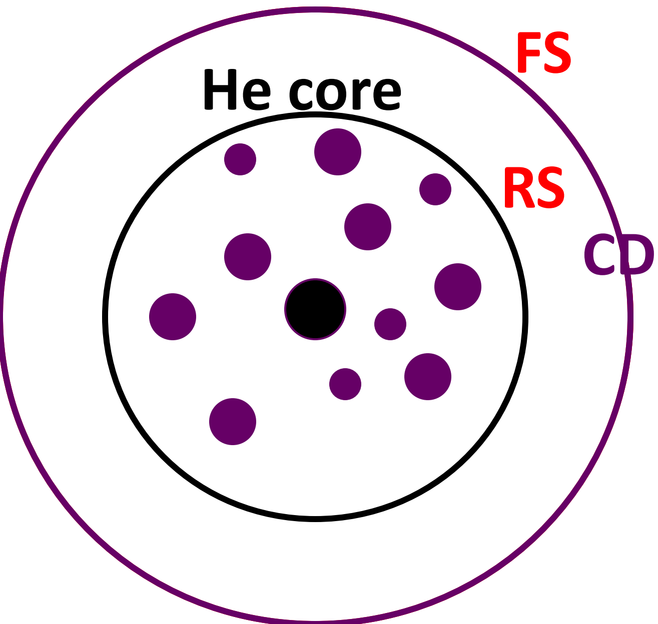
- A part of dust grains formed in the SN ejecta will be destroyed by the reverse shocks

what fraction of dust grains can survive to be injected?

- ➜ destruction efficiency depends on dust composition and size
- ➜ infrared to submm observations have few information on the the composition and size distribution of dust

Evolution of dust in SN remnants

$T = (1\text{-}2)\times10^4$ K
$n_{H,0} = 0.1\text{-}1$ cm^{-3}



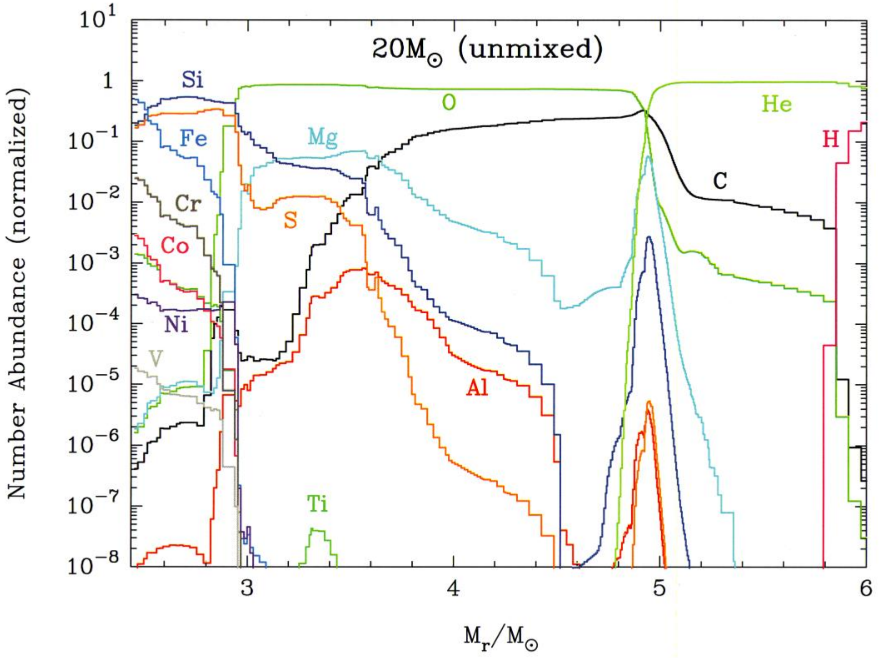
2. Theoretical Studies on Dust Formation in SNe

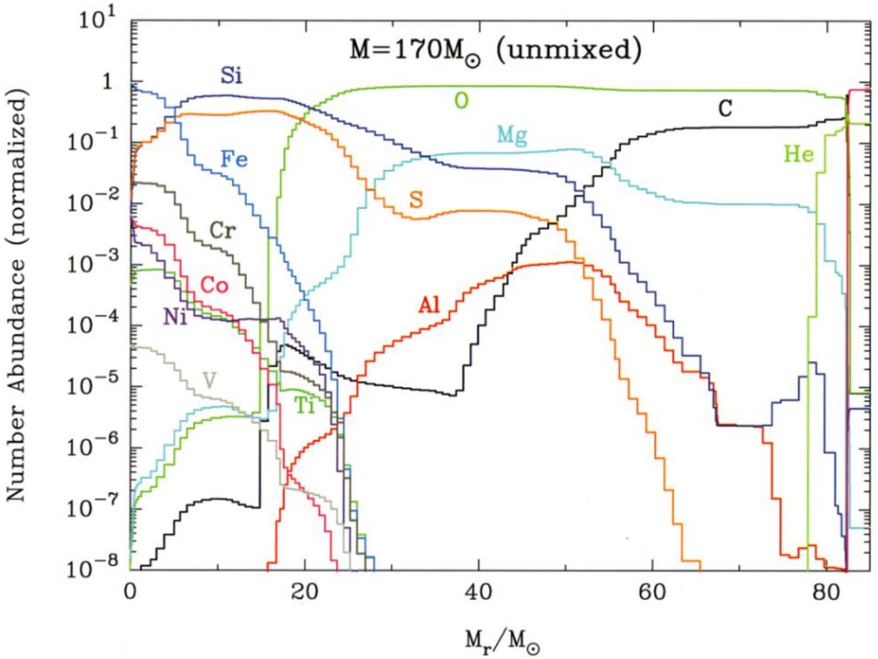
2-1. Dust formation in primordial SNe

Nozawa+2003, ApJ, 598, 785

○ Population III SNe model (Umeda & Nomoto 2002)

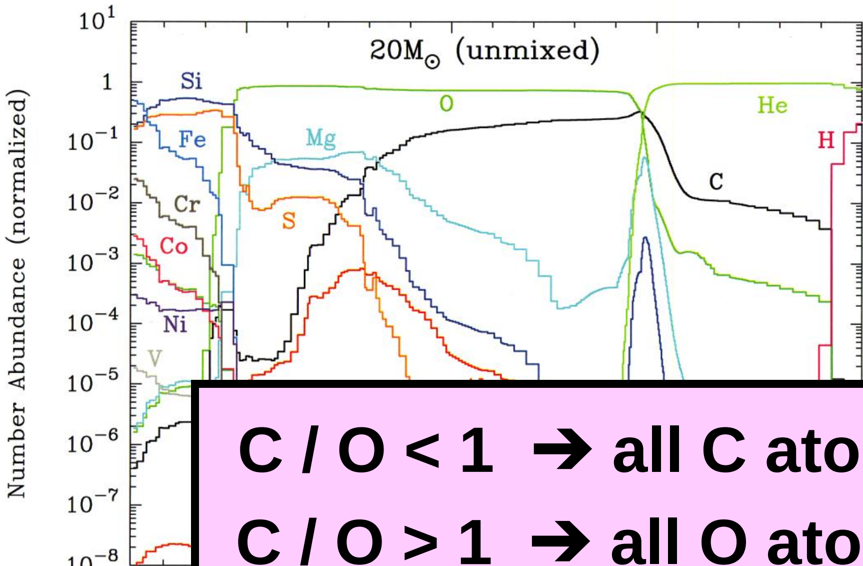
- SNe II : M_{ZAMS} = 13, 20, 25, 30 M_{sun} (E_{51}=1)
- PISNe : M_{ZAMS} = 170 M_{sun} (E_{51}=20), 200 M_{sun} (E_{51}=28)

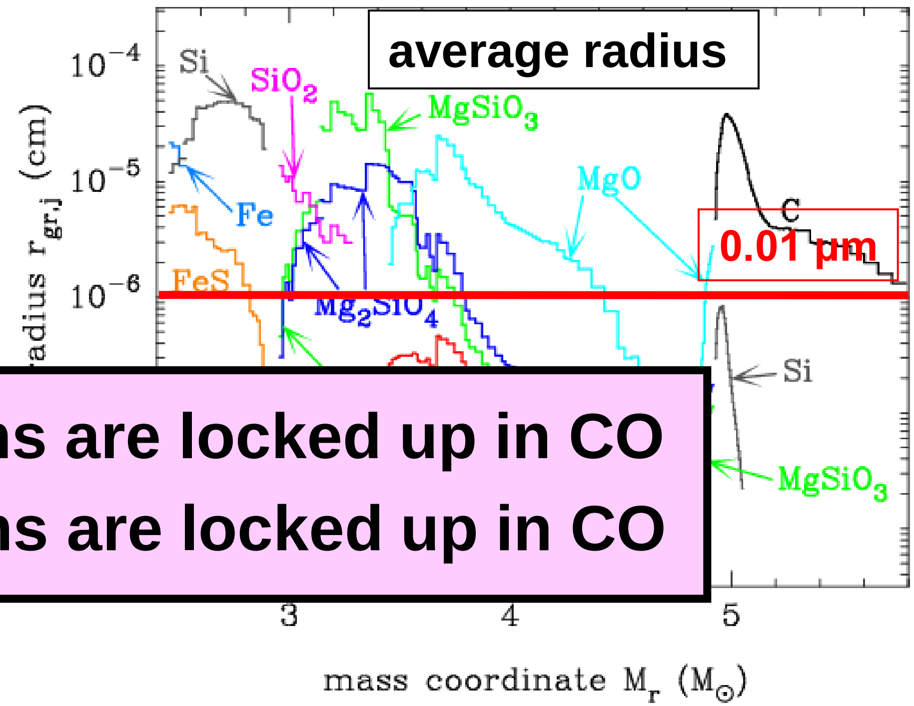




- nucleation and grain growth theory (Kozasa & Hasegawa 1987)
- no mixing of elements within the He-core
- complete formation of CO and SiO

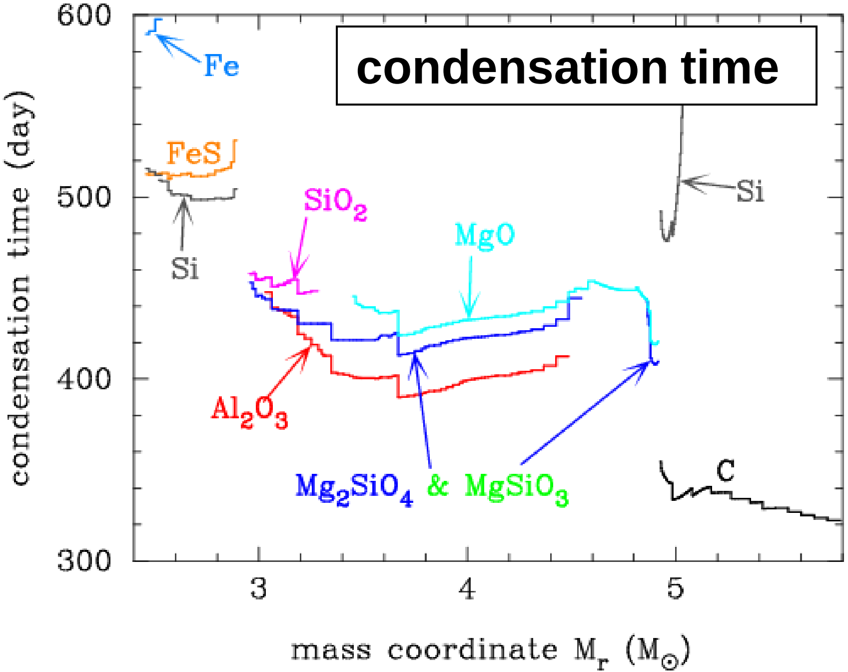
2-2. Dust formed in Type II-P SNe





C / O < 1 ➔ all C atoms are locked up in CO

C / O > 1 ➔ all O atoms are locked up in CO

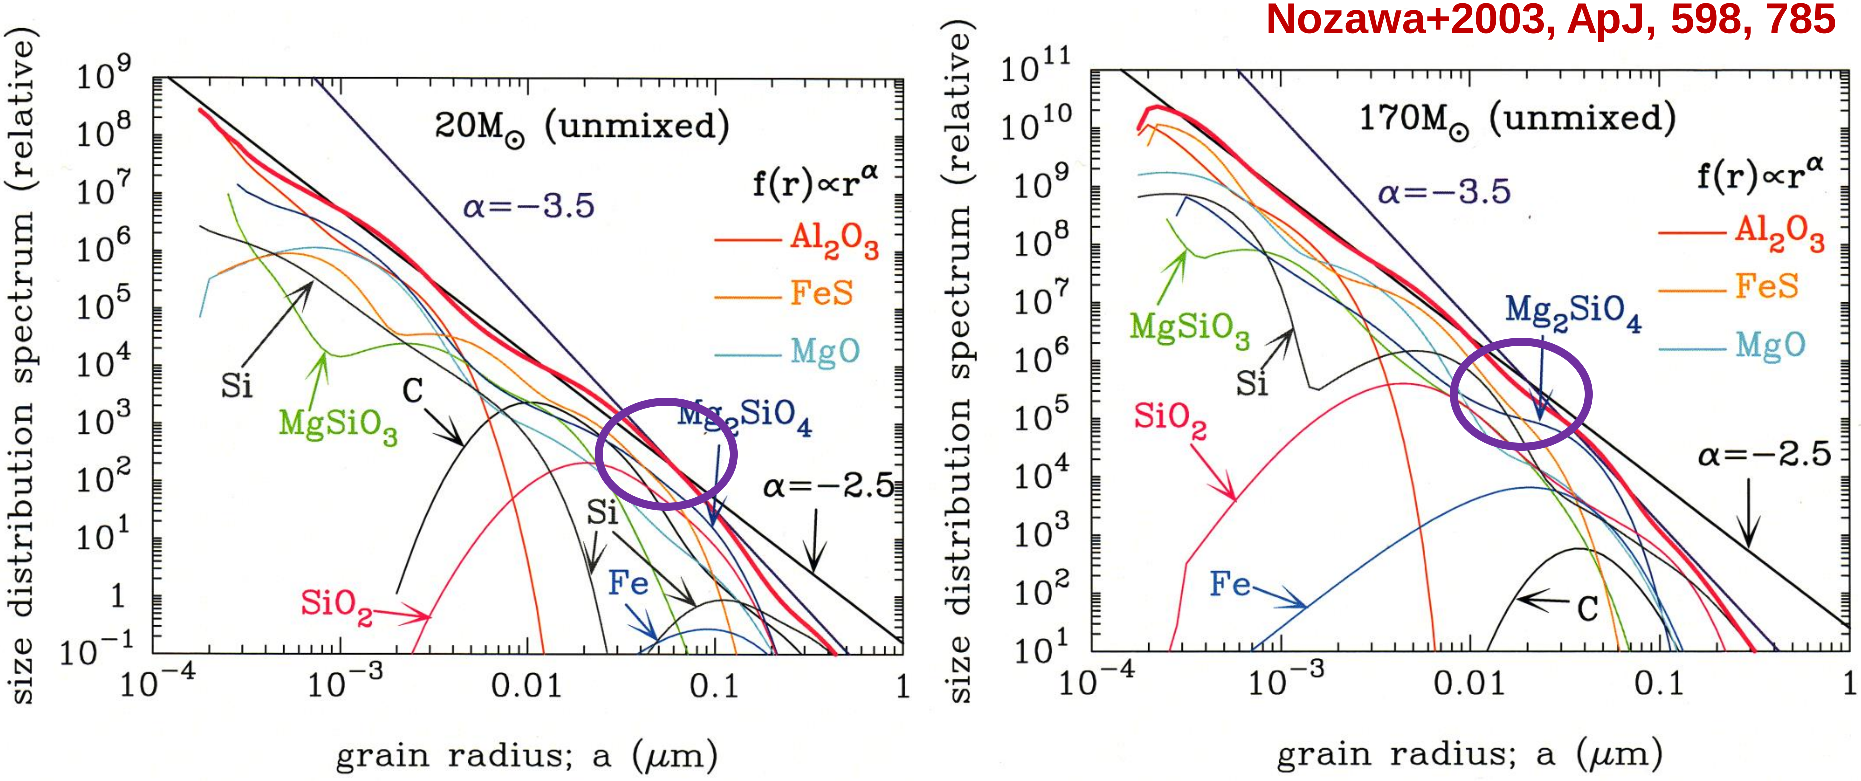


- a variety of grain species can condense according to elemental composition in each layer
- condensation time: **300-600d** after explosion
- average grain radii: **>~0.01 μm**

Nozawa+03, ApJ, 598, 785

2-3. Size distribution of newly formed dust

Nozawa+2003, ApJ, 598, 785

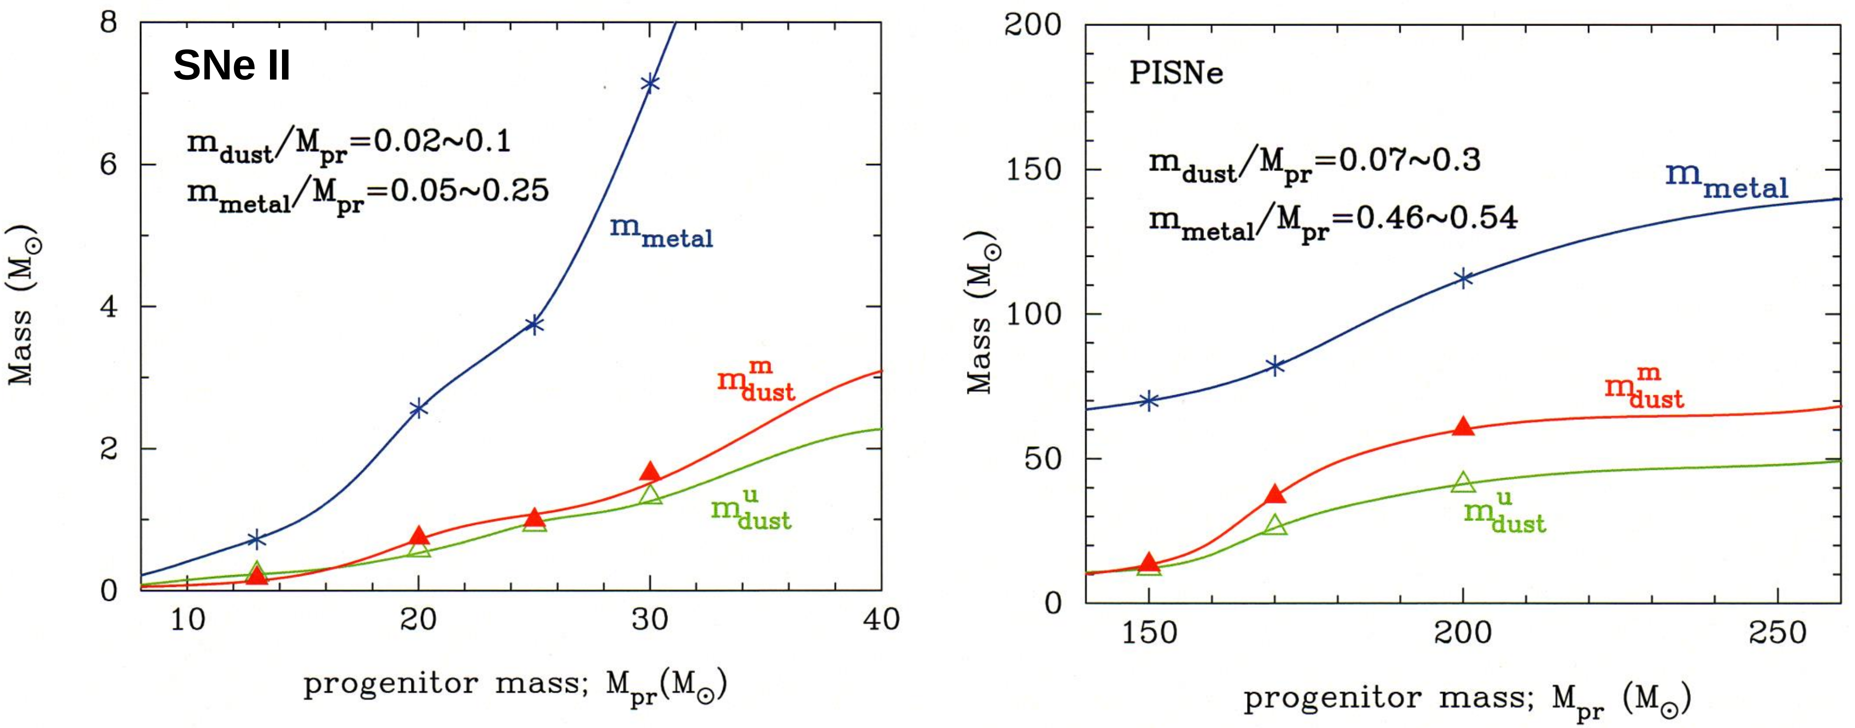


- C, SiO2, and Fe grains have lognormal-like size distribution, while the other grains have power-law size distribution

- The composition and size distribution of dust formed are almost independent of types of supernova

average grain radius is smaller for PISNe than SNe II-P

2-4. Total mass of dust formed in the ejecta

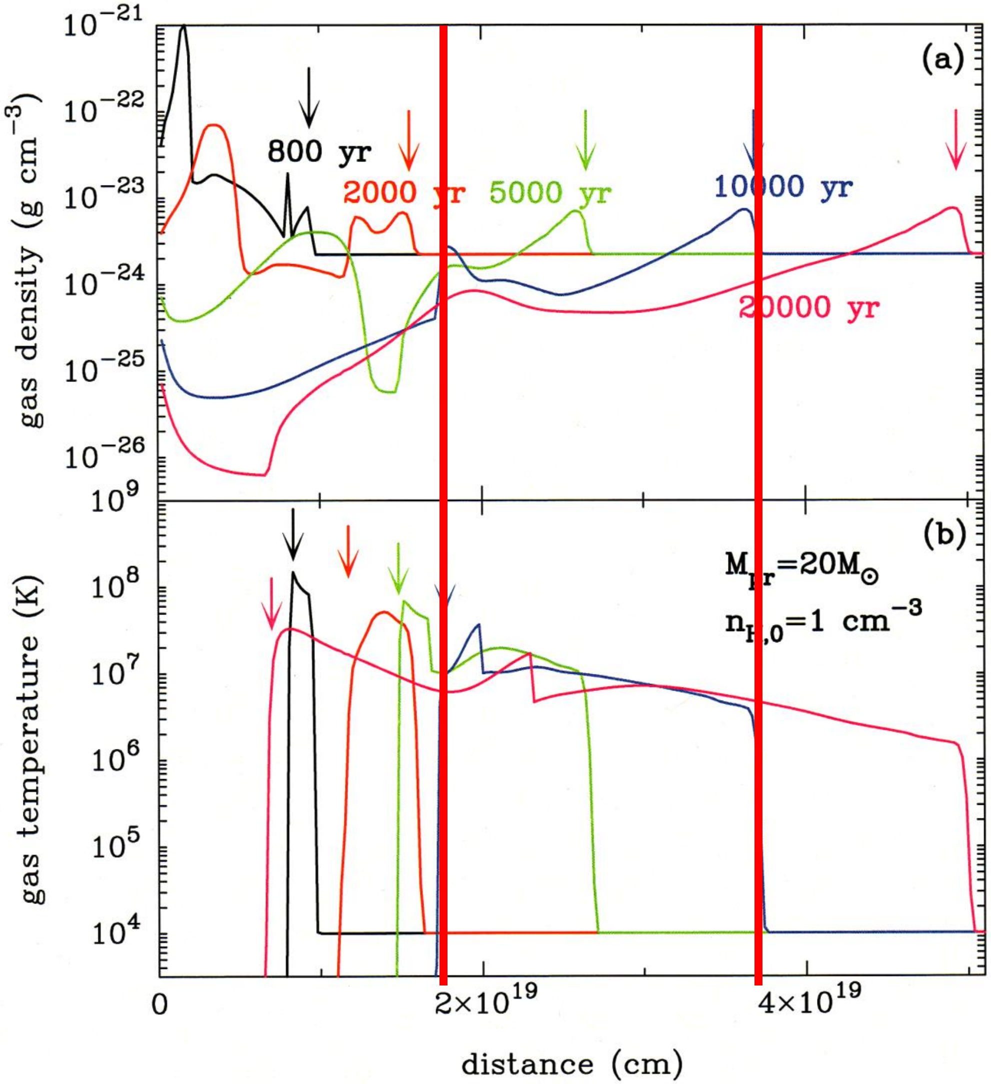


- Total mass of dust is higher for a higher progenitor mass (M_{ZAMS})
  SNe II : m_{dust} = 0.1-1.5 M_{sun}, m_{dust} / m_{metal} = 0.2-0.3
  PISNe : m_{dust} = 10-30 M_{sun}, m_{dust} / m_{metal} = 0.3-0.4

- almost all Fe, Mg, and Si are locked up in dust grains, while most of C and O remain in the gas-phase (such as CO)
  ➔ dust-to-metal mass ratio is not high for SNe II

2-5. Temperature and density of gas in SNRs

Nozawa+07, ApJ, 666, 955



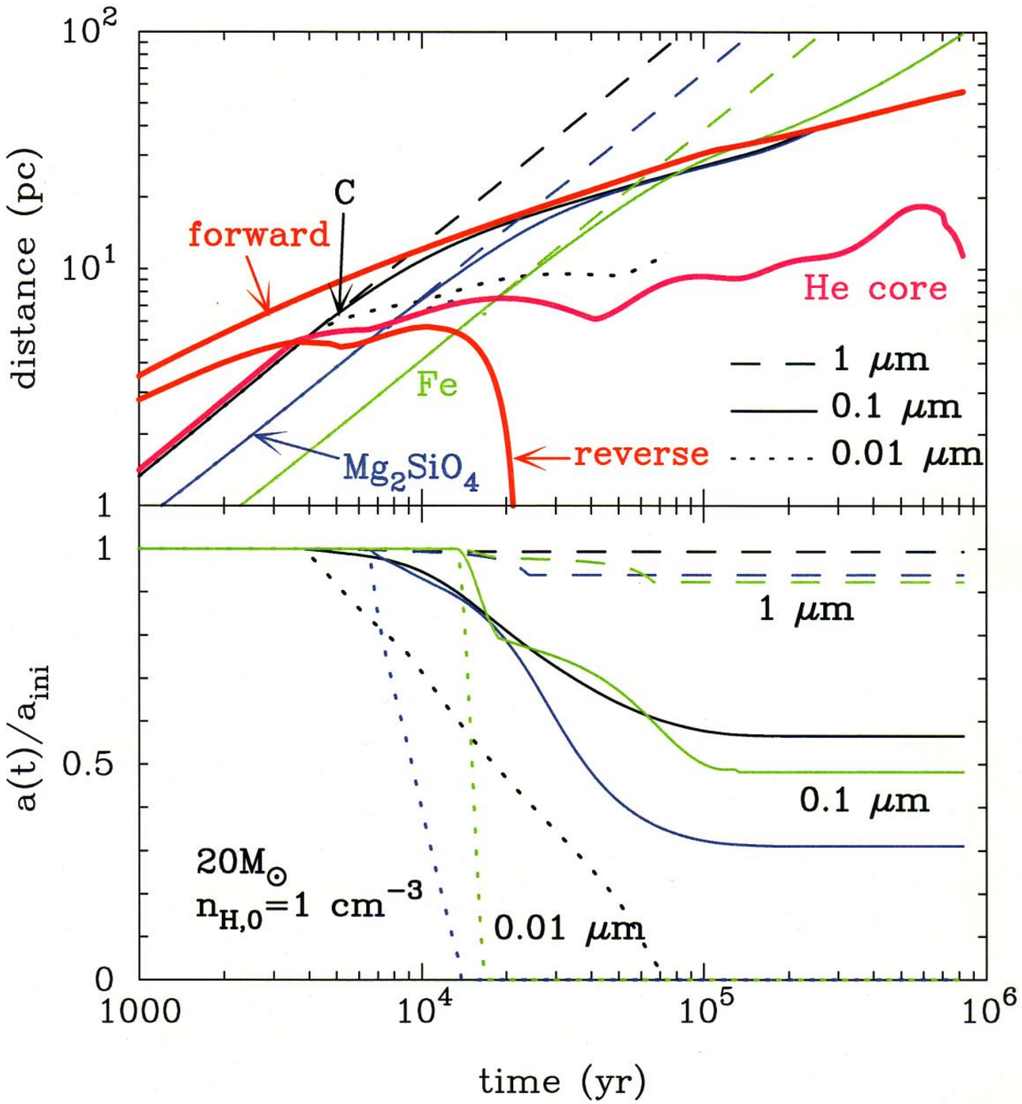
Model : M_{pr}= 20 Msun (E_{51}=1)
$n_{H,0}$ = 1 cm^{-3}

Downward-pointing arrows:
forward shock in upper panel
reverse shock in lower panel

The temperature of the gas swept up by the shocks
➔ 10^6-10^8 K
↓
Dust grains residing in the shocked hot gas are eroded by sputtering

2-6. Evolution of dust in SNRs

Nozawa+07, ApJ, 666, 955



Model : M_{pr}= 20 Msun (E_{51}=1)
$n_{H,0}$ = 1 cm^{-3}

Dust grains in the He core collide with reverse shock at (3-13)x10^3 yr

The evolution of dust heavily depends on the initial radius and composition

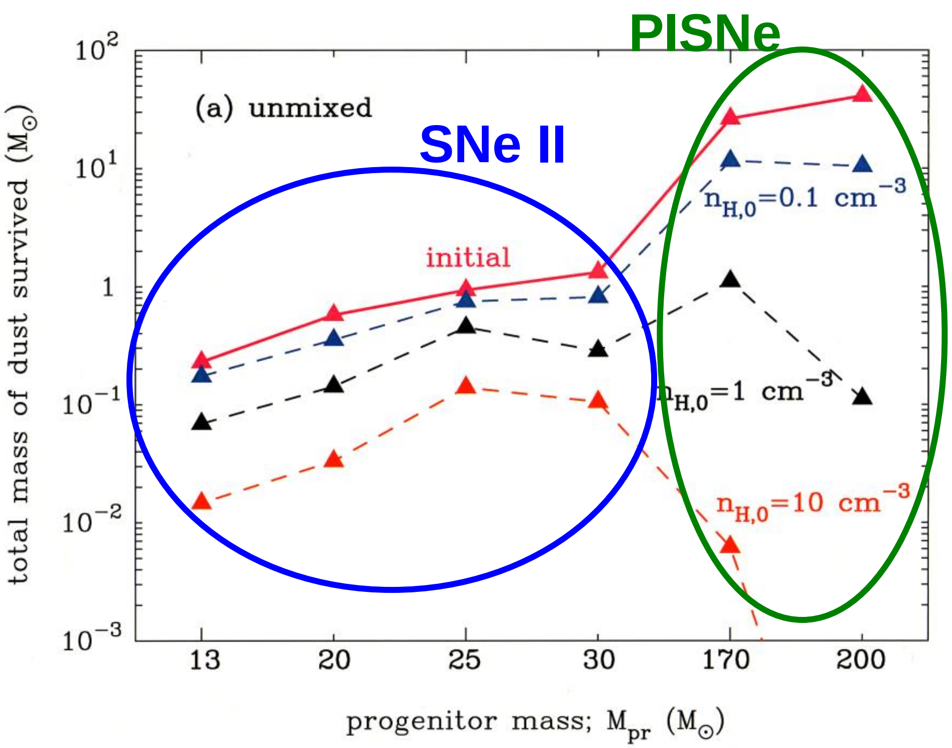
a_{ini} = 0.01 μm (dotted lines)
➔ completely destroyed

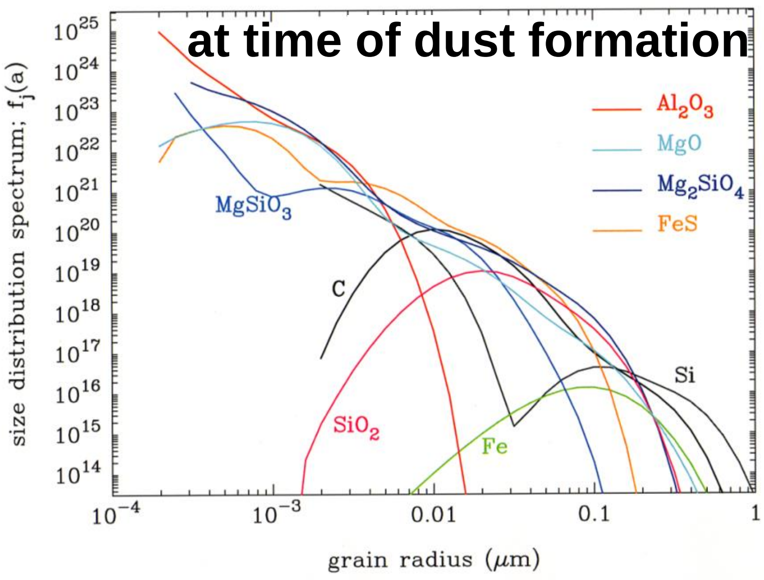
a_{ini} = 0.1 μm (solid lines)
➔ trapped in the shell

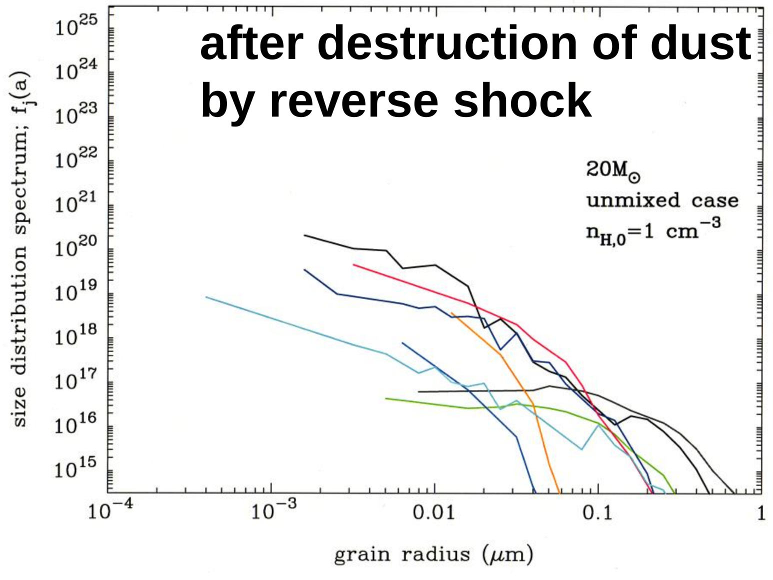
a_{ini} = 1 μm (dashed lines)
➔ injected into the ISM

2-7. Dust mass and size ejected from SN II-P

Nozawa+07, ApJ, 666, 955







total mass of dust surviving the destruction in Type II SNRs; 0.07-0.8 Msun ($n_{H,0}$ = 0.1-1 cm^{-3})

size distribution of dust after the shock-destruction is domimated by large grains (> 0.01 μm)

2-8. Summary of dust production in SNe

- Various grain species can condense in the ejecta

  ➔ almost all Fe, Mg, and Si are locked up in grains

- The fate of newly formed dust within SNRs strongly depends on the initial radii and compositions

- The size distribution of dust surviving the destruction in SNRs is weighted to relatively large size (> 0.01 μm).

- The total mass of dust injected into the ISM decreases with increasing the ambient gas density

  for $n_{H,0}$ = 0.1-1 cm^{-3}

  SNe II-P ➔ M_{dust} = 0.1-0.8 M_{sun}

➔ making significant contribution to dust budget
